An Introduction to Viruses

Lecturer
Dr Ashraf Khasawneh
Department of Biomedical Sciences

Virus infections are Universal

Introduction to Virology

- A virus is an obligate intracellular parasite containing genetic material surrounded by protein
- Virus particles can only be observed by an electron microscope

Introduction to Virology

- Recognizing the shape, size, and structure of different viruses is critical to the study of disease
 - Viruses have an inner core of nucleic acid surrounded by protein coat known as an envelope
 - −Most viruses range in sizes from 20 − 450 nanometers

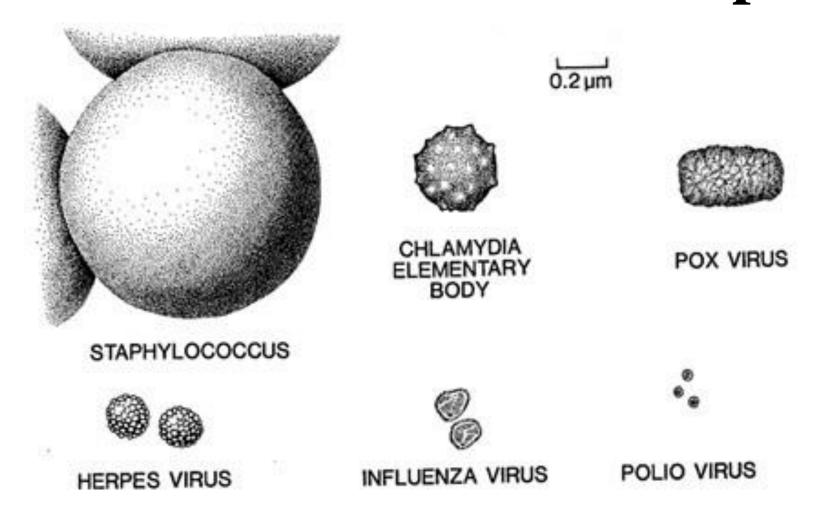

Viral Properties

- Viruses are inert (nucleoprotein) filterable Agents
- Viruses are obligate intracellular parasites
- Viruses cannot make energy or proteins independent of a host cell
- Viral genome are RNA or DNA but not both.
- Viruses have a naked capsid or envelope with attached proteins
- Viruses do not have the genetic capability to multiply by division.
- Viruses are non-living entities

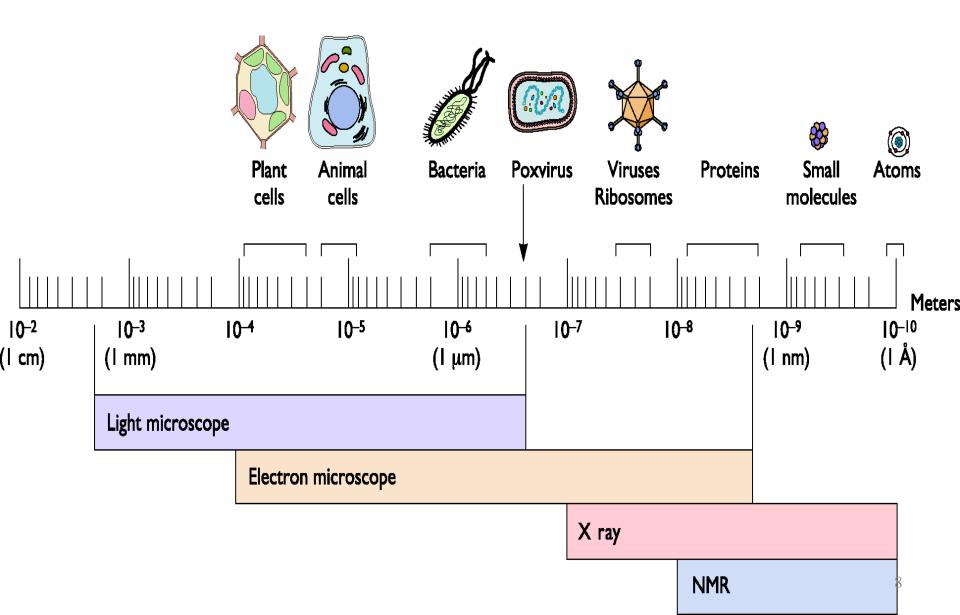

Virus vs. cells

Property	Viruses	Cells
Type of nucleic acid	DNA or RNA	DNA and RNA
Proteins	Few	Many
Lipoprotein membrane	Enveloped	Cell membrane
	present in	present in
	some viruses	all cells
Ribosomes	Absent	Present
Mitochondria	Absent	Present in eukaryotic cells
Enzymes	None or few	Many
Multiplication by binary fission	No	Yes (most cells)

Viruses are Ultramicroscopic

The size of viruses

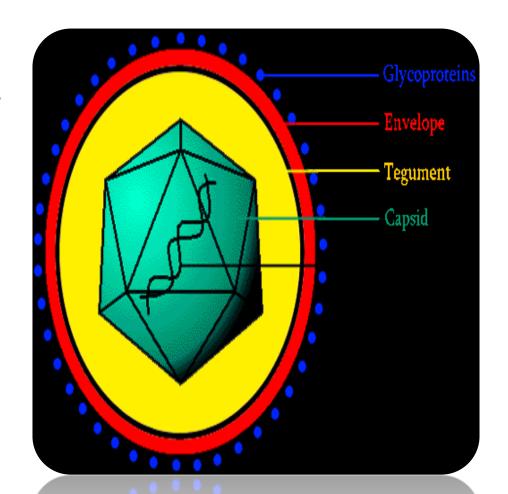

VIRAL STRUCTURE – SOME TERMINOLOGY

- virus particle = virion
- protein which coats the genome = capsid
- capsid usually symmetrical
- capsid + genome = nucleocapsid
- may have an envelope

Virion

- The complete infectious unit of virus particle
- Structurally mature, extracellular virus particles.

Viral Structure - Overview

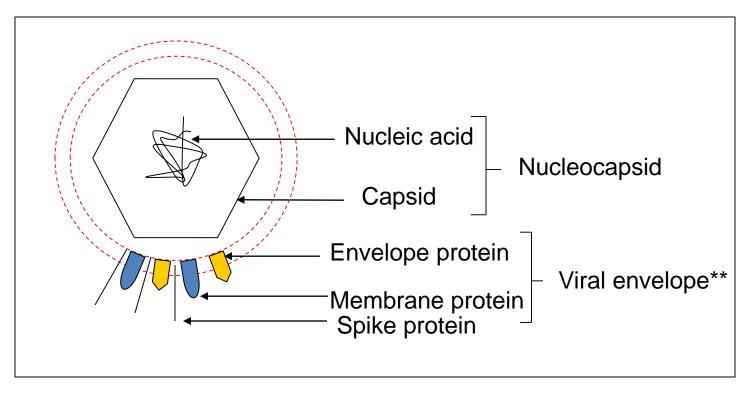

Fig 1. Schematic overview of the structure of animal viruses

^{**} does not exist in all viruses

Distinguishing characteristics of viruses

- Obligate intracellular parasites
- Extreme genetic simplicity
- Contain DNA or RNA
- Replication involves disassembly and reassembly
- Replicate by "one-step growth"

Naming viruses

- No taxa above Family (no kingdom, phylum, etc)
- Classified based on structures, size, nucleic acids, host species, target cells.
- 19 families of animal viruses (6 DNA, 13 RNA)
- Family name ends in viridae
- Subfamily ends in virinae
- Genus name ends in virus
- Species
 - > Example
 - Family Herpesviridae
 - Subfamily Herpesvirinae
 - Genus Simplex virus
 - Common name herpes virus (Herpes simplex virus I (HSV-I)
 - Disease fever blisters, cold sores

How are viruses named?

- Based on:
 - the disease they cause

poliovirus, rabies virus

- the type of disease

murine leukemia virus

- geographic locations

Sendai virus, Coxsackie virus

- their discovers

Epstein-Barr virus

- how they were originally thought to be contracted

dengue virus ("evil spirit"), influenza virus (the "influence" of bad air)

- combinations of the above

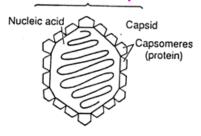

Rous Sarcoma virus

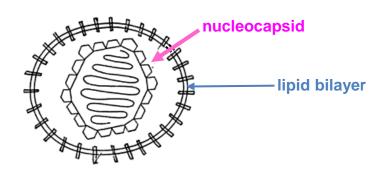

Virus particle = virion Herpesviridae Poxviridae Adenoviridae Papovaviridae Hepadnaviridae Parvoviridae **DNA VIRUSES** Orthomyxoviridae Coronaviridae Paramyxoviridae Arenaviridae Retroviridae Filoviridae Picornaviridae Caliciviridae Togaviridae Reoviridae Rhabdoviridae Flaviviridae Bunyaviridae 100 nm

RNA VIRUSES

5 BASIC TYPES OF VIRAL STRUCTURE

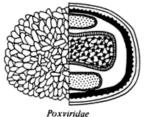

icosahedral nucleocapsid

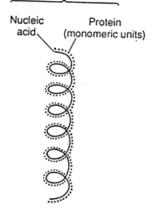

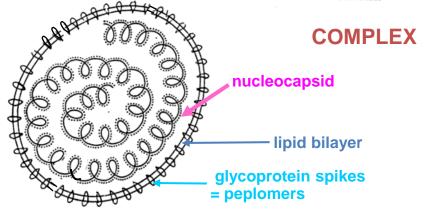

ICOSAHEDRAL

ENVELOPED ICOSAHEDRAL

helical nucleocapsid

HELICAL

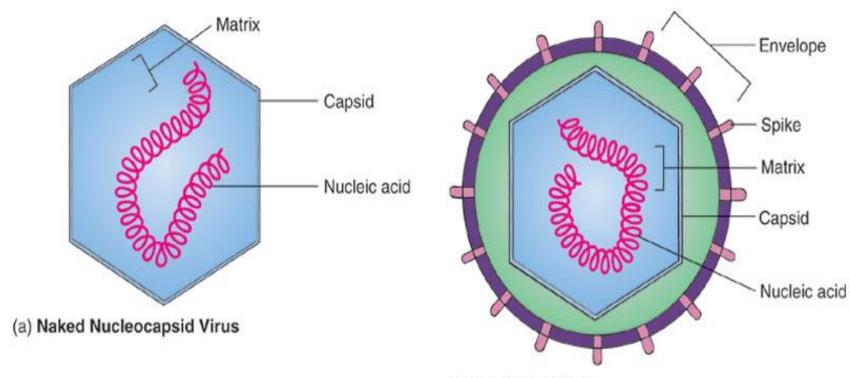

ENVELOPED HELICAL

Viral Structure

- Varies in size, shape and symmetry
- 3 types of capsid symmetry:
 - Cubic (icosahedral)
 - Has 20 faces, each an equilateral triangle. Eg. adenovirus
 - Helical
 - Protein binds around DNA/RNA in a helical fashion eg. Coronavirus
 - Complex
 - Is neither cubic nor helical eg. poxvirus

VIRAL STRUCTURE (virion)

Copyright @ The McGraw-Hill Companies, Inc. Permission required for reproduction or display.

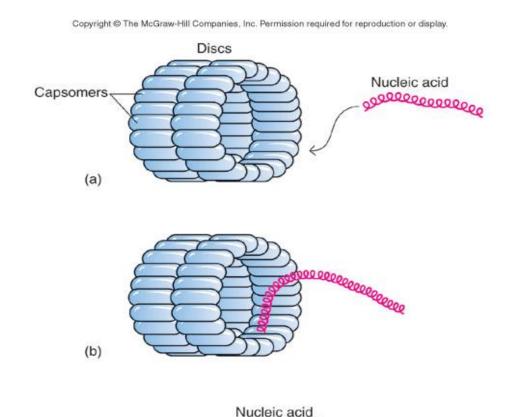

- 1. Protect genome during passage from one cell to another
- 2. Aid in entry process
- 3. Package enzymes for early steps of infection

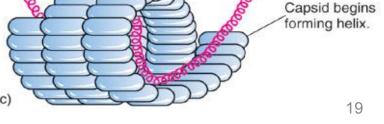

(b) Enveloped Virus

CAPSID STRUCTURE

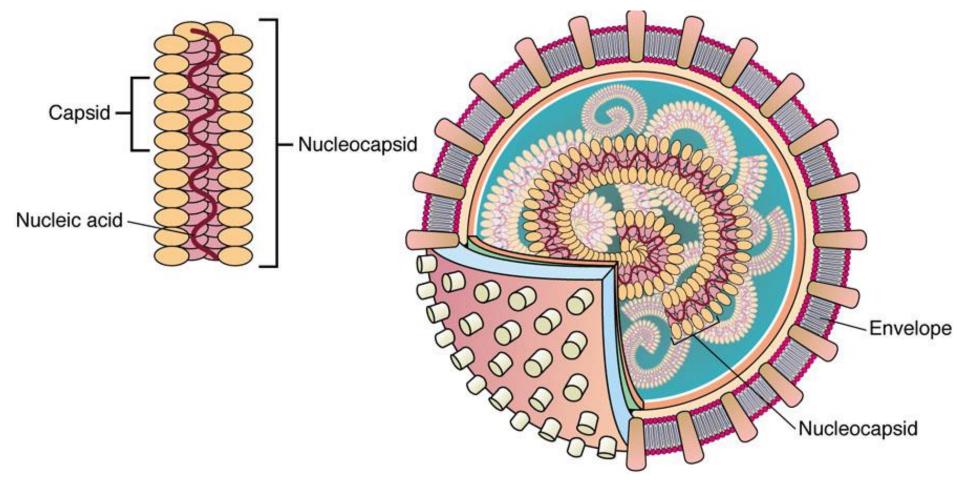

1. Helical capsid

- Rod-shaped capsomers
- Coil around hollow center
- Nucleic acid is kept inside – wound-up within tube (Helix)

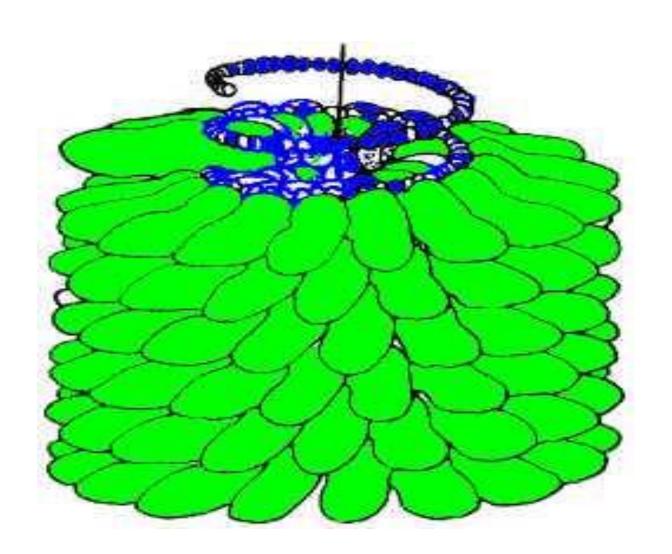

Morphological types

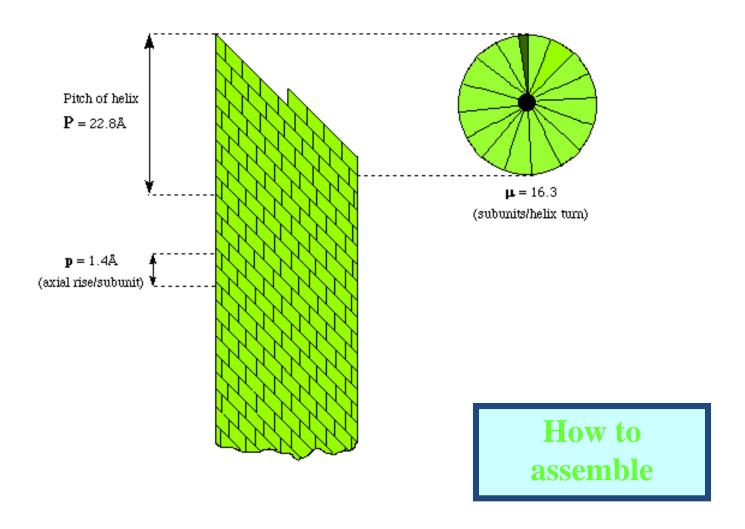

Helical – capsid surrounds DNA like hollow tube Ex: Influenza, measles, rabies (enveloped)

Helical symmetry

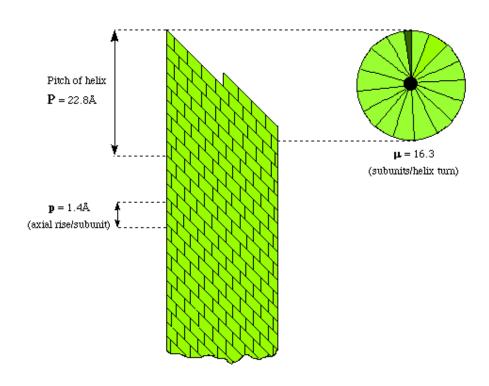

Helical symmetry

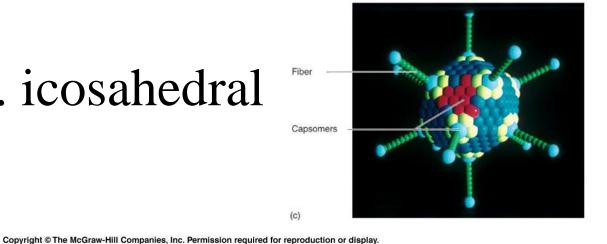

Helical symmetry

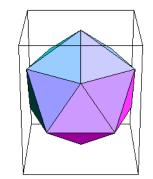

In 1955, Fraenkel, Conrat, and Williams demonstrated that tobacco mosaic virus (TMV) spontaneously formed when mixtures of purified coat protein and its genomic RNA were incubated together.

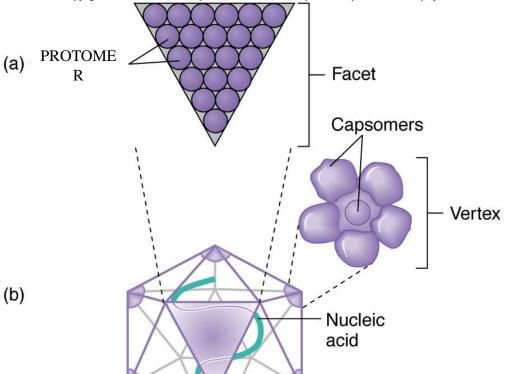

TMV, a filamentous virus

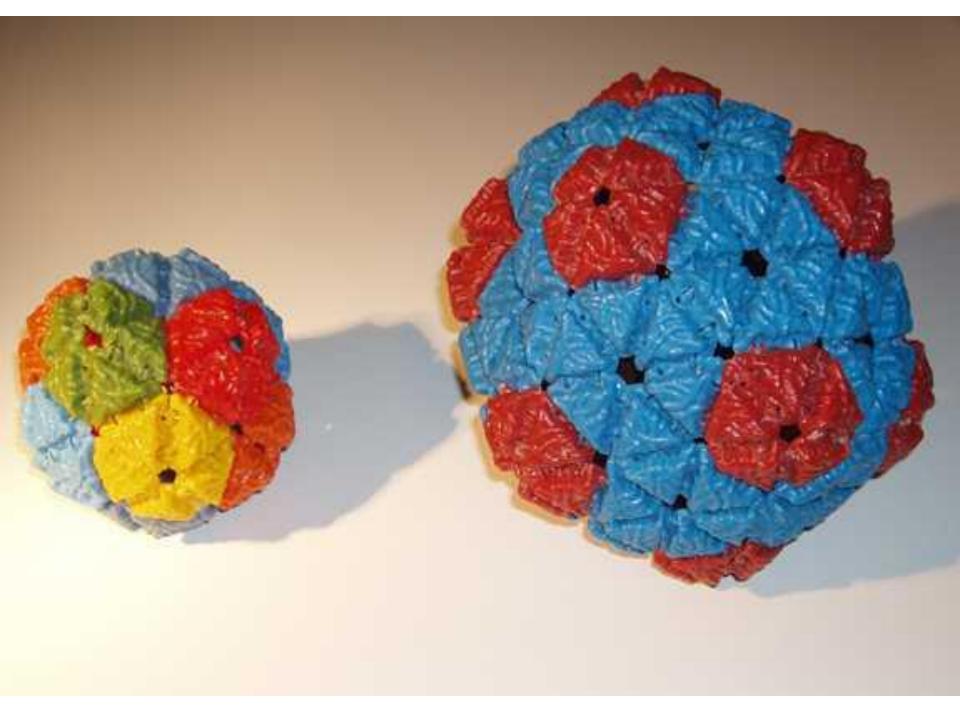

2. icosahedral

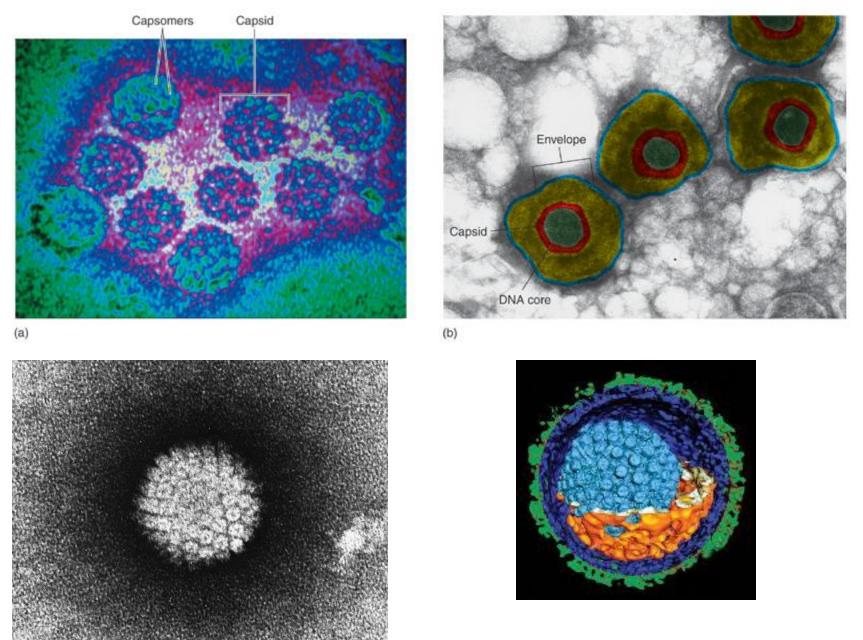

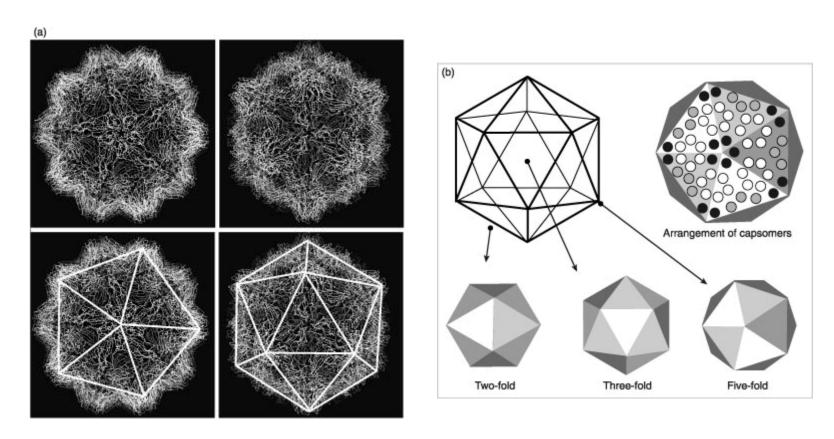

- 20-sided with 12 corners
- Vary in the number of capsomers
- Each capsomer may be made of 1 or several proteins
- Some are enveloped

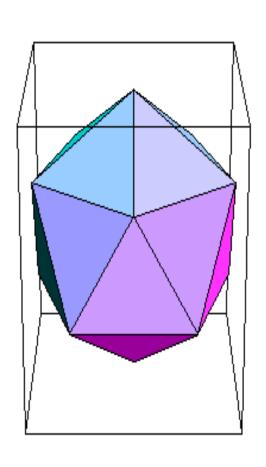

Icosahedral capsids

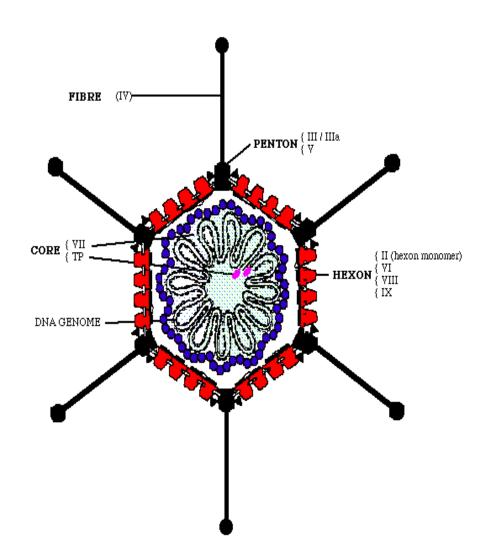

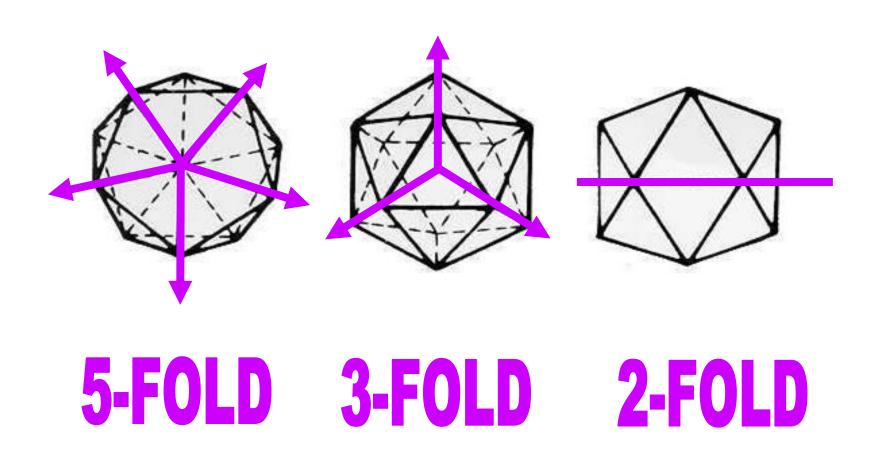

a) Crystallographic structure of a simple icosahedral virus.

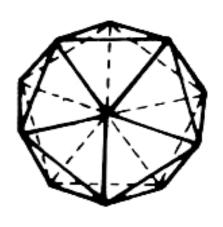

b) The axes of symmetry

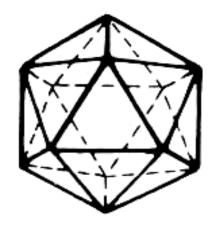

Cubic or icosahedral symmetry

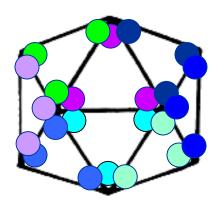

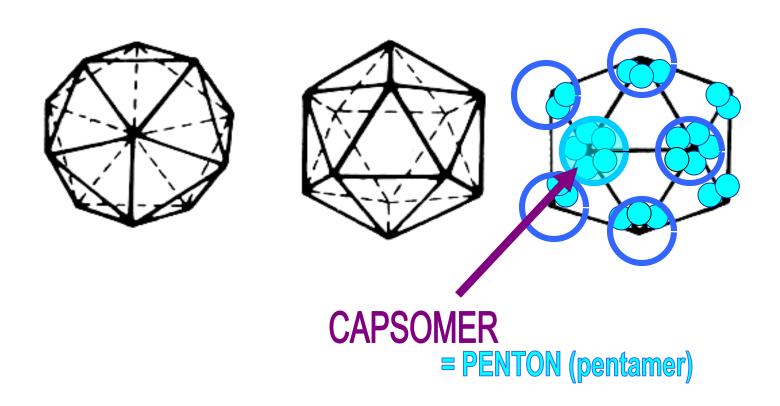

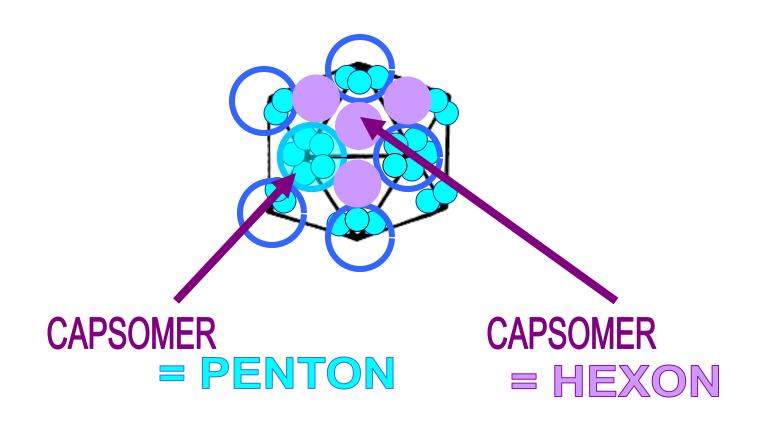

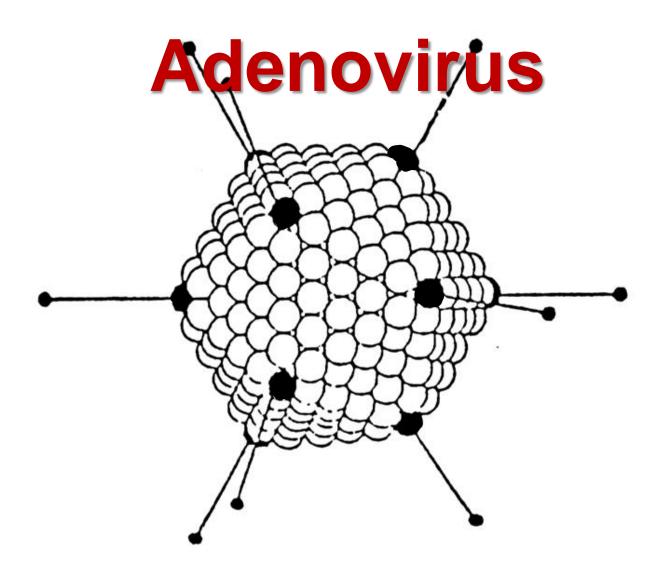

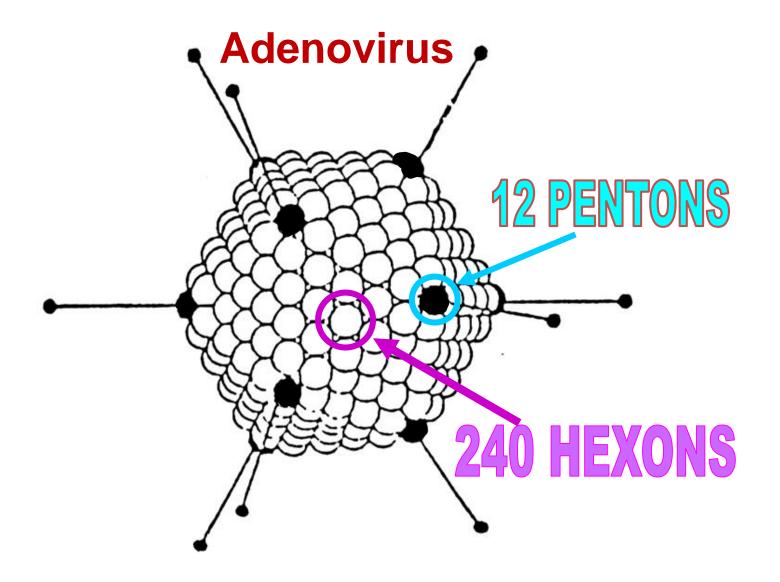

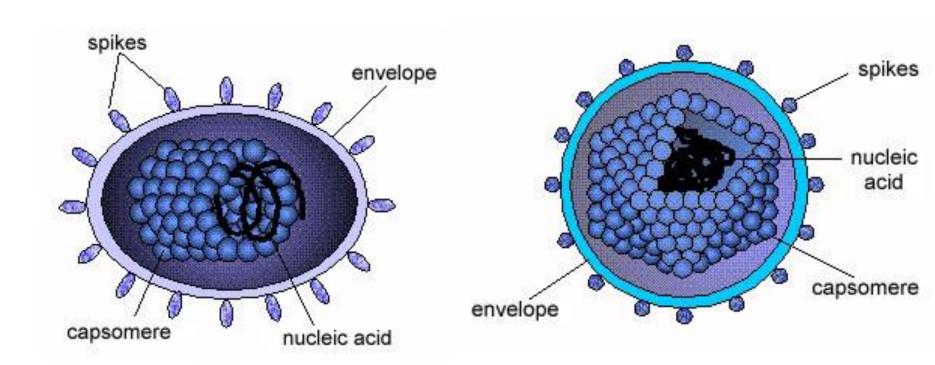

Enveloped helical virus

Enveloped icosahedral virus

Helical

California Encephalitis Virus
 Coronavirus
 Hantavirus
 Influenza Virus (Flu Virus)
 Measles Virus (Rubeola)
 Mumps Virus
 Para influenza Virus
 Rabies Virus
 Respiratory Syncytial Virus(RSV)

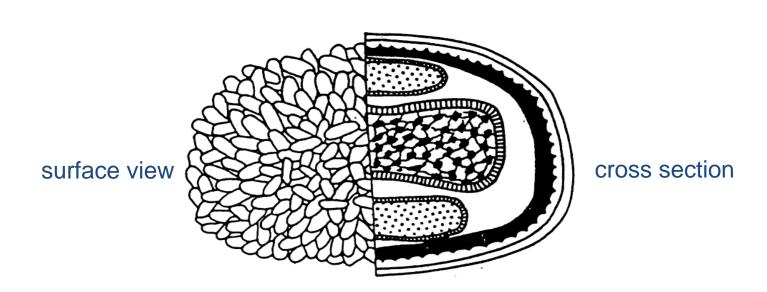

Icosahedral

 Adeno-associated Virus (AAV) Adenovirus B19 Coxsackievirus - A Coxsackievirus - B Cytomegalovirus (CMV) Eastern Equine Encephalitis Virus (EEEV) **Echovirus** Epstein-Barr Virus (EBV) Hepatitis A Virus (HAV) Hepatitis B Virus (HBV) Hepatitis C Virus (HCV) Hepatitis Delta Virus (HDV) Hepatitis E Virus (HEV)

• Herpes Simplex Virus 1 (HHV1) Herpes Simplex Virus 2 (HHV2) Human Immunodeficiency Virus (HIV) Human T-lymphotrophic Virus (HTLV) Norwalk Virus Papilloma Virus (HPV) Polio virus Rhinovirus Rubella Virus Saint Louis Encephalitis Virus Varicella-Zoster Virus (HHV3) Western Equine Encephalitis Virus (WEEV) Yellow Fever Virus

Complex viruses

- Have additional or special structures
- Examples:
- Poxviruses lack normal capsid instead,
 layers of lipoprotiens and fibrils on surface

A bacteriophage

• A bacteriophage is any one of a number of viruses that infect bacteria. They do this by injecting genetic material, which they carry enclosed in an outer protein capsid. The genetic material can be ssRNA, dsRNA, ssDNA, or dsDNA ('ss-' or 'ds-' prefix denotes single-strand or double-strand) along with either circular or linear arrangement.

Phage - viruses have a polyhedral head, helical tail and fibers for attachment.

Copyright @ The McGraw-Hill Companies, Inc. Permission required for reproduction or display. 240-300 nm. Nucleic acid Capsid head 200 nm Nucleic acid Collar Outer Sheath envelope Soluble protein antigens Lateral body Tail fibers (a) Tail Base plate pins (c)

Classification of viruses

- Nucleic acid
- Capsid
- Presence of envelope
- Replication strategy

CLASSIFICATION NUCLEIC ACID

- RNA or DNA
- segmented or non-segmented
- linear or circular
- single-stranded or double-stranded
- if single-stranded RNA
 - is genome mRNA (+) sense or complementary to mRNA (-) sense

ENVELOPE

- OBTAINED BY BUDDING THROUGH A CELLULAR MEMBRANE (except poxviruses)
- POSSIBILITY OF EXITING CELL WITHOUT KILLING IT
- CONTAINS AT LEAST ONE VIRALLY CODED PROTEIN
 - ATTACHMENT PROTEIN
- LOSS OF ENVELOPE RESULTS IN LOSS OF INFECTIVITY

Properties of naked viruses

- Stable in hostile environment
- Not damaged by drying, acid, detergent, and heat
- Released by lysis of host cells
- Can sustain in dry environment
- Can infect the GI tract and survive the acid and bile
- Can spread easily via hands, dust, fomites, etc
- Can stay dry and still retain infectivity
- Neutralizing mucosal and systemic antibodies are needed to control the establishment of infection

Naked viruses (Non Enveloped)

Adeno-associated Virus (AAV)
 Adenovirus

B19

Coxsackievirus - A

Coxsackievirus - B

Echovirus

Hepatitis A Virus (HAV)

Hepatitis E Virus (HEV)

Norwalk Virus

The Baltimore classification system

Based on genetic contents and replication strategies of viruses. According to the Baltimore classification, viruses are divided into the following seven classes:

- 1. dsDNA viruses
- 2. ssDNA viruses
- 3. dsRNA viruses
- 4. (+) sense ssRNA viruses (codes directly for protein)
- 5. (-) sense ssRNA viruses
- 6. RNA reverse transcribing viruses
- 7. DNA reverse transcribing viruses

where "ds" represents "double strand" and "ss" denotes "single strand".

Virus Classification - the Baltimore classification

- All viruses must produce mRNA, or (+) sense RNA
- A complementary strand of nucleic acid is (–) sense
- The Baltimore classification has + RNA as its central point
- Its principles are fundamental to an understanding of virus classification and genome replication, but it is rarely used as a classification system in its own right

Viral genome strategies

- dsDNA (herpes, papova, adeno, pox)
- ssDNA (parvo)
- •dsRNA (reo, rota)
- •ssRNA (+) (picorna, toga, flavi, corona)
- •ssRNA (-) (rhabdo, paramyxo, orthomyxo,
- bunya, filo)
- •ssRNA (+/-) (arena, bunya)
- •ssRNA (+RTase) (retro, lenti)

Sub-viral agents

Satellites

- Contain nucleic acid
- Depend on co-infection with a helper virus
- May be encapsidated (satellite virus)
- Mostly in plants, can be human e.g. hepatitis delta virus
- If nucleic acid only = virusoid

Viroids

- Unencapsidated, small circular ssRNA molecules that replicate autonomously
- Only in plants, e.g. potato spindle tuber viroid
- Depend on host cell polII for replication, no protein or mRNA

Prions

- No nucleic acid
- Infectious protein e.g. BSE

Viroids & Prions

Viroids

- ss RNA genome and the smallest known pathogens.
- Affects plants

Prions

- Infectious particles that are entirely protein.
- No nucleic acid
- Highly heat resistant
- Animal disease that affects nervous tissue
- Affects nervous tissue and results in
 - Bovine spongiform encepahltits (BSE) "mad cow disease",
 - scrapie in sheep
 - kuru & Creutzfeld-Jakob Disease (CJD) in humans

Viroids

- Viroids are small (200-400nt), circular RNA molecules with a rod-like secondary structure which possess no capsid or envelope which are associated with certain plant diseases. Their replication strategy like that of viruses they are obligate intracellular parasites.
- Viroids do not encode any proteins and unlike satellites they are not dependent on the presence of another virus

Viroid replication

- Viroids utilize cellular RNA polymerases for their replication
- Replication is performed by "rolling circle mechanism"
- The resulting long RNA molecule is cut in pieces and ligated either autocatalytically or by cellular factors (depending on a viroid)
- So in a sense, at least some viroids are ribozymes...

Examples of plants, infected with various viroids

Hepatitis δ virus — a chimeric molecule, half viroid, half satellite

- Viroid like properties
- Rod-like RNA molecule
- Rolling circle replication
- Self-cleaving activty

- Satellite like properties
- Encodes a protein, which is necessary both for encapsidation and replication
- Dependent on presence another virus HBV
- Genome larger than for viroids (1640 nt)

Prions

 Prions are rather ill-defined infectious agents believed to consist of a single type of protein molecule with no nucleic acid component. Confusion arises from the fact that the prion protein & the gene which encodes it are also found in normal 'uninfected' cells. These agents are associated with diseases such as Creutzfeldt-Jakob disease in humans, scrapie in sheep & bovine spongiform encephalopathy (BSE) in cattle.

Prions

Prions are proteinaceous transmissible pathogens responsible for a series of fatal neurodegenerative diseases (in humans, Creutzfeld-Jakob disease and kuru, in animals, bovine spongioform encephalopathy)

A prion (**pro**teinaceous **in**fectious particle, analogy for virion) is a type of infectious agent that does not carry the genetic information in nucleid acid!

Prions are proteins with the pathological conformation that are believed to infect and propagate the conformational changes of the native proteins into the the abnormally structured form

Disease name	Natural host	Prion name	PrP isoform
Scrapie	Sheep, goat	Scrapie prion	OvPrP ^{Sc}
Transmissible mink encephalopathy (TME)	Mink	TME prion	MkPrP ^{Sc}
Chronic wasting disease (CWD)	Elk, mule deer	CWD prion	MDePrP ^{Sc}
Bovine spongioform encephalopathy (BSE)	Cattle	BSE prion	BovPrP ^{Sc}
Feline spongioform encephalopathy (FSE)	Cat	FSE prion	FePrP ^{Sc}
Exotic unguale encephalopathy (EUE)	Greater kudu, nyala	EUE prion	NyaPrP ^{Sc}
Kuru	Human	Kuru prion	HuPrP ^{Sc}
Creutzfeldt-Jakob disease (CJD)	Human	CJD prion	HuPrPSc
Gerstmann-Straussler- Scheinker syndrome (GSS)	Human	GSS prion	HuPrP ^{Sc}
Fatal familial insomnia (FFI)	Human	FFI prion	HuPrP ^{Sc}

Prion diseases: rare neurodegenerative disorders (one person per million)

1. Sporadic (85 %)

In the sixth or seventh decade, rapidly progressive (death in less than a year)

Creutzfeldt-Jakob disease (CJD)

2. Familial (inherited-15%)

Mutations in the PrP gene that favour the transition from the cellular form to the pathological form of PrP

Gerstmann-Straussler-Scheinker disease (GSS), fatal familial insomnia (FFI)

3. Transmissible (rare; a source of great concern)

Propagation of kuru disease in New Guinea natives (ritualistic cannibalism)

Recently, it has been discovered that BSE had been transmitted to humans in Europe after consumption of infected beef, producing a variant of the CJD called vCJD

Transmissible spongioform encephalopathy (TSE)=prion disease

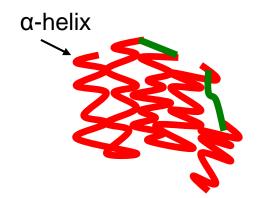

A group of progressive conditions that affect the brain and nervous system of humans and animals and are transmitted by prions

The pathology: vacuolar degeneration, neuronal loss, astrocytosis and amyloid plaque formation

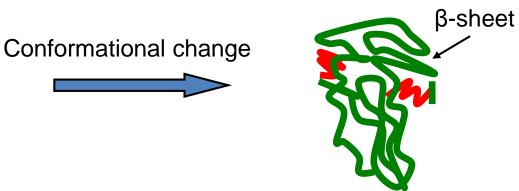

The clinical signs: loss of motor functions (lack of coordination, ataxia, involuntary jerking movements), personality changes, depression, insomnia, confusion, memory problems, dementia, progressive tonic paralysis, death

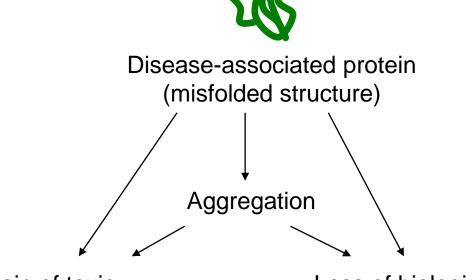

Definitive diagnostic test: biopsy of brain tissue (histopathological examination and immunostaining for PrPSc)

There is no cure

Normal protein (folded structure)

Gain of toxic activity

Loss of biological function

PrP^C

The normal protein

is called PrP^c (for cellular)

is a transmembrane glycoprotein (neurons, lymphocytes); its function is unknown; it binds Cu²⁺ (regulation its homeostasis)

has dominant secundary structure α-helix

is easily soluble

is monomeric and easily digested by proteases

is encoded by a gene designated PRNP located on the chromosome 20

PrPSc

The abnormal, disease-producing protein

is called PrPSc (for scrapie)

has the same amino acid sequence (primary structure)

has dominant secundary structure β-sheets

is insoluble

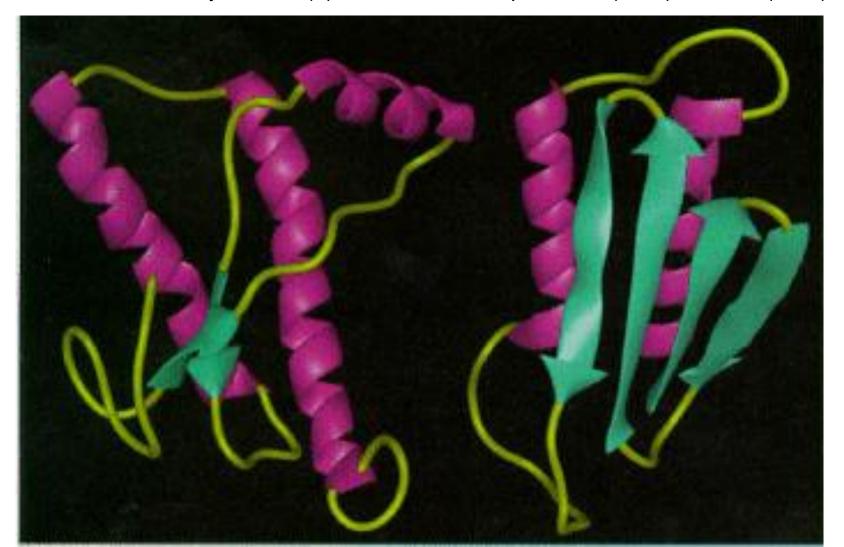

is multimeric and resistant to digestion by proteases

When PrPsc comes in contact with PrPc, it converts the PrPc into more of itself These molecules bind to each other forming aggregates

Molecular models of the structure of:

PrP^C Predominantly α-helix (3)

PrPSc β-sheets (40%), α-helix (30%)

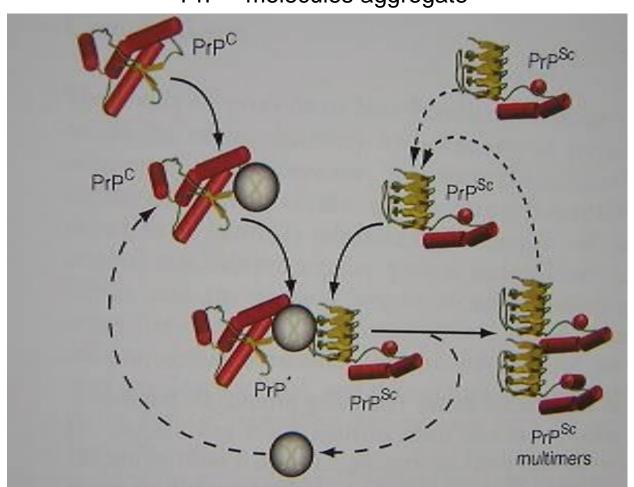

Replication cycle

The presence of an initial PrPSc: exogenous (infectious forms) or endogenous (inherited or sporadic forms)

This first prion will initiate PrPSc accumulation by sequentially converting PrPC molecules into PrPSc in replication cycle

PrPSc molecules aggregate

Summary

The prions are proteins that carry information for self-reproduction (contradict the central dogma of modern biology)

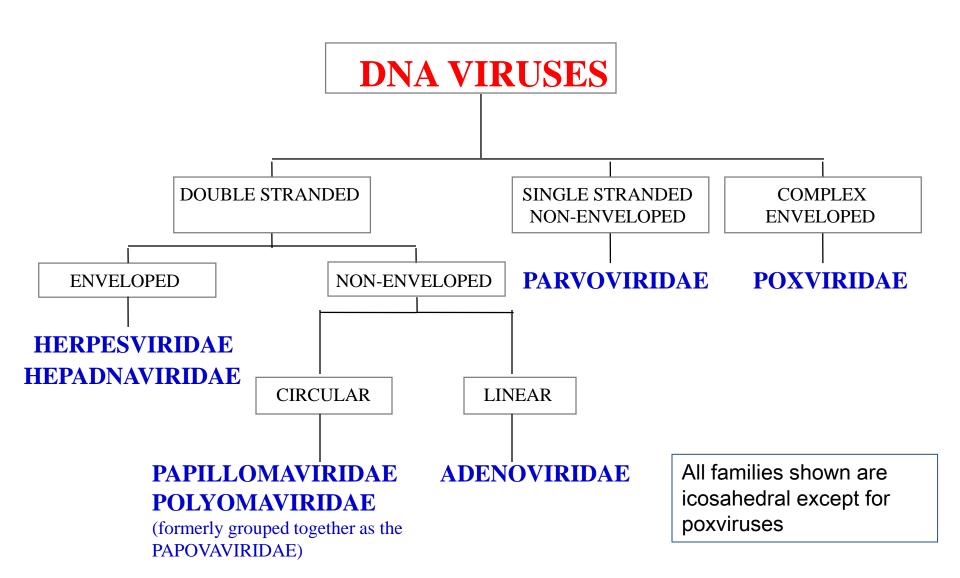

The prions are expressed in cells of healthy humans and animals; their abnormal conformations (PrPSc) are insoluble, resistent to digestion and aggregate

The PrP^{Sc} attacks the native prion PrP^C, changes its conformation into an abnormal form and causes an exponential production of insoluble proteins; they aggregate and form the fibrillar structure

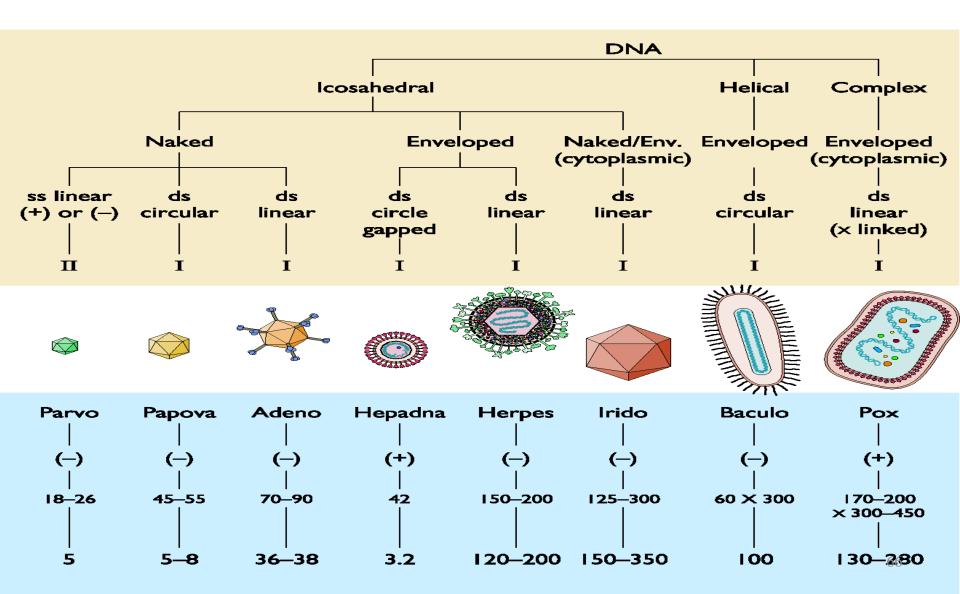

Prion disease are rare fatal degenerative disorders; a portion of them can be transmitted; this mechanism is not clear (e.g. transmision of BSE to human)

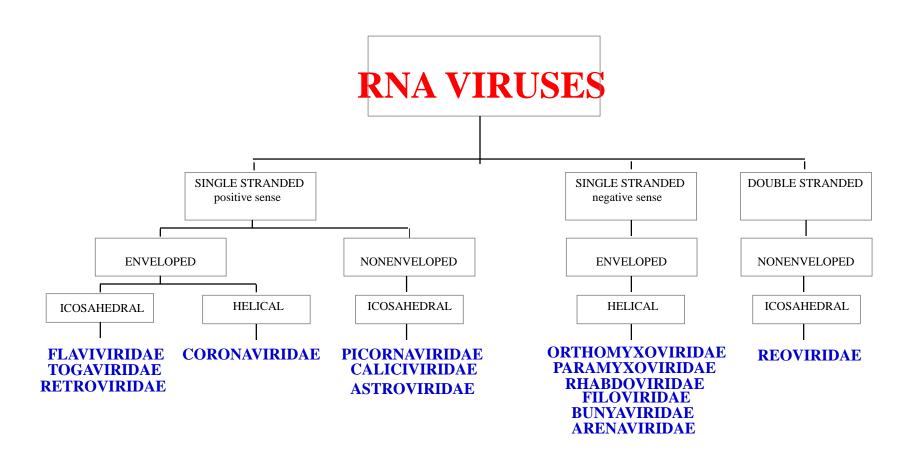

One part of the prion protein can cause apoptosis, or programmed cell death

Prions induce no immune reactions within the human

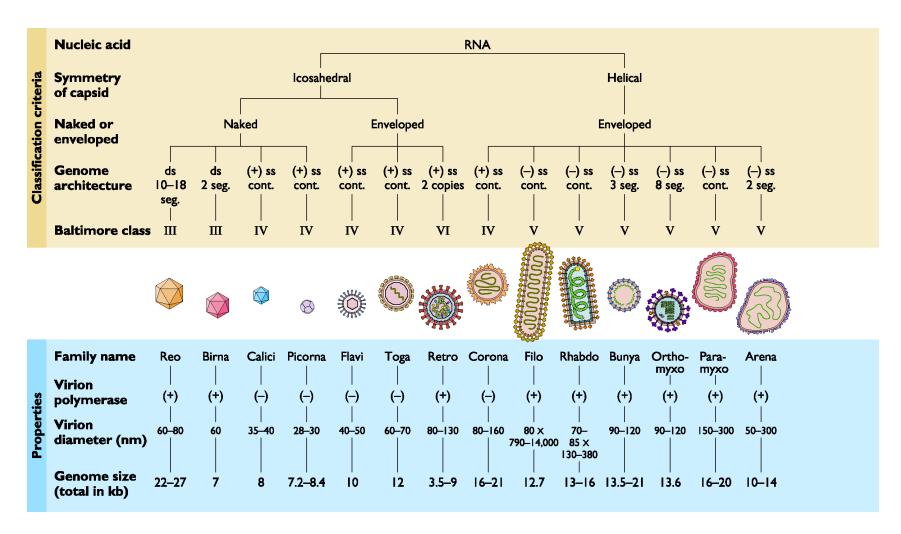

DNA viruses

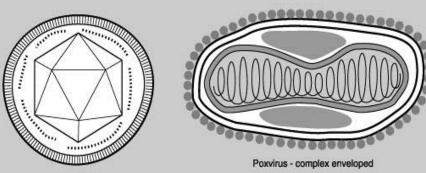

RNA viruses

From Principles of Virology Flint et al ASM Press

(a) Some DNA Viruses

100 nm

Herpesvirus Icosahedral enveloped

Parvovirus ssDNA, Icosahedral

Plant geminivirus SS DNA (some need two capsids to contain full genome

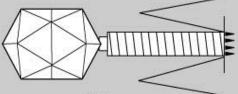

T7 Phage lcosahedral head

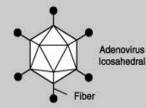

Papovavirus Icosahedral

φX174 SSDNA

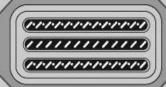

T4 Phage Elongated icosahedral head

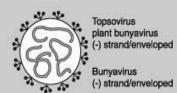

Plant caulimovirus related to hepadnavirus)

Insect baculovirus complex

(b) Some Helical RNA Viruses

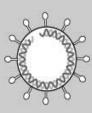

Orthomyxovirus (-) strand/enveloped

Arenavirus (-) strand/enveloped

Coronavirus (+) strand/ enveloped

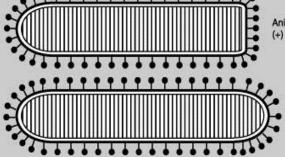

Paramyxovirus (-) strand/ enveloped

100 nm

Animal rhabdovirus (+) strand/enveloped

Plant rhabdovirus (-) strand/enveloped

Some Icosahedral RNA Viruses

Plant carmovirus, tymovirus, sobemovirus, necrovirus, etc. (+) strand RNA related to picomaviruses

Togavirus

Picornavirus (+) strand

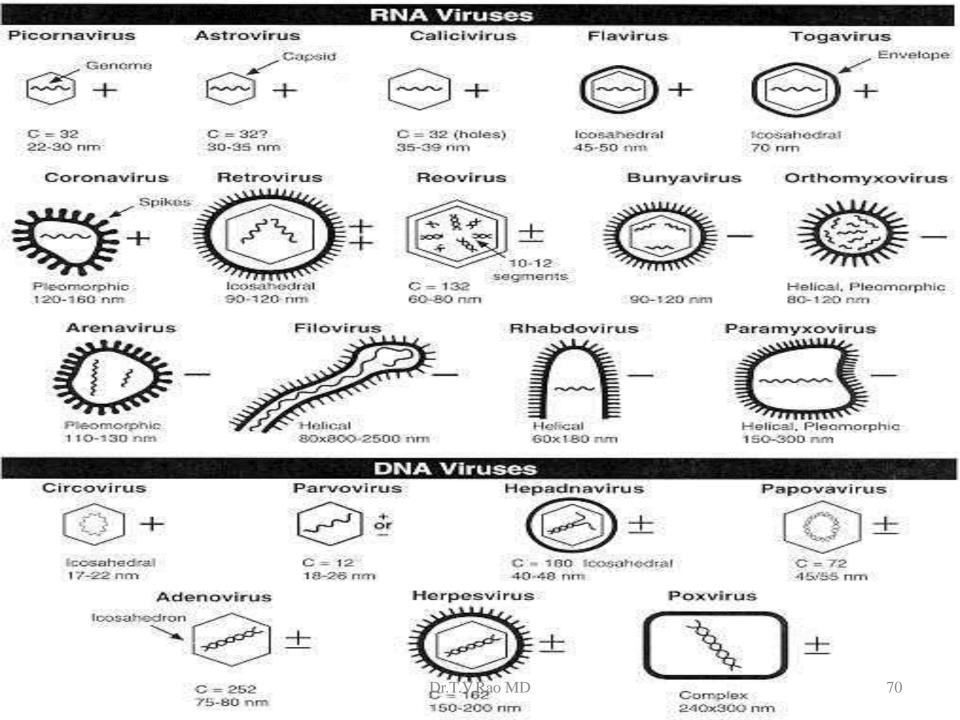

Flavivirus (+) strand/enveloped

Retrovirus Enveloped/DNA step (+) Strand

Plant Reovirus dsRNA

BASIC STEPS IN VIRAL LIFE CYCLE

- ADSORPTION
- PENETRATION
- UNCOATING AND ECLIPSE
- SYNTHESIS OF VIRAL NUCLEIC ACID AND PROTEIN
- ASSEMBLY
- RELEASE
